Report Downloads and NDC Notifications

A practical overview of the user experience, background processing, configuration layers, and notification workflow.

Report download experience

The report is prepared in the background so the user can leave the page.

The user selects the report filters and file format, starts the download, and sees a clear status transition from **Queuing report...** to **Report ready**.

UI example: the first panel shows the queued state; the second panel shows a ready report and a download link.

Report download feature flow

Request, background processing, storage, status polling, and final download.

The download is asynchronous. The API creates a request quickly, while the report is generated by a scheduled background worker and stored before the client downloads it.

Failure path: a generation or storage error changes the request to FAILED so the UI can show an error instead of waiting indefinitely.

NDC notification configuration

Three configuration layers work together before an email can be sent.

The NDC notification feature is controlled through scheme, DFSP, and user-level settings. A notification is delivered only when the required gates are enabled.

● Effective notification gate

Scheme enabled + active DFSP/currency threshold + eligible user preference = notification can be delivered.

Configuration and approval screens determine the settings; the scheduled worker and dispatcher enforce them at runtime.

NDC notification workflow

Detailed runtime path from threshold evaluation to email delivery.

The runtime workflow has two coordinated jobs: the threshold worker decides whether an alert event should exist, and the notification dispatcher delivers that event to eligible users.

Operational visibility

Evaluation results, alert events, job execution records, and notification delivery logs provide traceability. Pending, failed, and retryable deliveries remain visible for operational review.

What the platform does automatically

A short reference for explaining the two features during knowledge sharing.

Both features separate the user interaction from longer-running backend work. This protects the user experience and gives operations clear status and audit points.

Report download

- Request is saved with PENDING status.
- Scheduler and worker generate the report in the background.
- Large output can be batched or split into a ZIP.
- Ready file is stored in object storage.
- Client polls status and receives a pre-signed link.

NDC notifications

- Scheme, DFSP/currency, and user settings act as gates.
- Scheduled worker compares current usage with the threshold.
- New breach creates an alert; duplicates are suppressed.
- Dispatcher selects eligible recipients and sends email.
- Delivery logs and retries support operational follow-up.

Key message for clients: the portal accepts the request immediately, processes work safely in the background, and gives the user a clear status and controlled delivery outcome.
